Final Project Submission

- Student name: Justin Grisanti
- Student pace: self-paced
- Scheduled project review date/time: 6/20/2022
- Instructor name: Claude Fried
- Blog post URL: https://justingrisanti.github.io/spotify_recommendation_system (https://justingrisanti.github.io/spotify_recommendation_system)

Section 1: Business Understanding

Context:

Spotify is an audio streaming and media services platfrom, created in 2006. It is one of the largest music streaming service providers with over 406 million monthly active users, including 180 million paying subscribers, as of December 2021.

Spotify offers digital copyright restricted recorded music and podcasts, including more than 82 million songs, from record labels and media companies. As a freemium service, basic features are free with advertisements and limited control, while additional features, such as offline listening and commercial-free listening, are offered via paid subscriptions. Spotify is currently available in 180+ countries as of October 2021. Users can search for music based on artist, album, or genre, and can create, edit, and share playlists.

Two of the most important aspects of Spotify that has led to its popularity are its music discovery functionalities, and playlist creation fostering a new social aspect to music listening. In a 2021 How-To Geek article called "6 Awesome Spotify Features You Should Be Using," 3 of the 6 features are related to playlists, and one speaks about music discovery. One of these features related to music discovery is called "Enhance." Enhance allows you to discover new tracks that might best fit one of your existing playlists. For example, if you have a playlist of a collection of 80s rock songs, Enhance might suggest that you add "Eye of the Tiger" by Survivor.

Business Problem:

Music is now one of the easiest forms of media to consume, due to smartphone technology allowing users to access millions of songs at their fingertips. However, with all of these choices, it is hard to know where to begin when it comes to finding new music that matches someone’s preferences, and users may become overwhelmed when trying to find music.

The solution to this problem is to create a recommendation system from scratch that can reperform the functionality of Enhance, which is to use a selection of songs from a playlist and use content-based filtering to suggest a list of songs that are similar.

The stakeholders of this project are Spotify, music-listeners, DJs, and other music-related occupations.

The main purpose of this recommendation system is inferential, meaning that this model should be able infer information about songs from a given playlist and then to predict songs that a user will likely add to that same playlist.

Section 2: Data Understanding

Now that I have developed a overall business understanding, I will take a deeper dive into the data that I will be using for this project.

In [1]:
```
# Import relevant libraries

import pandas as pd
from numpy.random import seed
seed(123)
import numpy as np
import random
import shutil
import math
import statistics as stat
import os
from os.path import exists
import datetime
import seaborn as sns
from sklearn.metrics.pairwise import cosine_similarity as cos
from sklearn.impute import SimpleImputer
import matplotlib.pyplot as plt
import sklearn as sk
from sklearn.preprocessing import OneHotEncoder, MinMaxScaler
from sklearn.feature_extraction.text import TfidfVectorizer
import json
from pandas.io.json import json_normalize
import spotipy
from spotipy.oauth2 import SpotifyClientCredentials
import time
import config
sp = spotipy.Spotify(auth_manager=SpotifyClientCredentials(client_
                                                            client_
import sqlite3
conn = sqlite3.connect('Data/music_recs.db')
cur = conn.cursor()
from pyspark import SparkContext
from pyspark.sql import SparkSession
import dataframe_image as dfi

import sys
import re
import collections
```

In [2]:
```
# Set input path for os functions

input_path = 'Data/spotify_million_playlist_dataset/data/'
```

In [3]:
```
# Check how many items are in the data folder. There are 1000 file

list_files = os.listdir(input_path)
number_files = len(list_files)
print(number_files)
```

```
1019
```

In [4]:
```
# View a handful of files to see their types

os.listdir(input_path)[0:5]
```

Out[4]:
```
['mpd.slice.549000-549999.json',
 'mpd.slice.613000-613999.json',
 'mpd.slice.115000-115999.json',
 'mpd.slice.778000-778999.json',
 'mpd.slice.290000-290999.json']
```

As we can see above, it appears that we have 1000 json files in our data folder. Each file appears to have 1000 records each, which means there are 1 million songs in our dataset. After trying to load the first file, it was too large for my computer to handle. Instead, I will load the first playlist to see its contents.

In [5]:

```python
# Open json file to see formatting

test = open(input_path+'mpd.slice.0-999.json')
data_0_999 = json.load(test)
data_0_999['playlists'][0]
```

Out[5]:

```
{'name': 'Throwbacks',
 'collaborative': 'false',
 'pid': 0,
 'modified_at': 1493424000,
 'num_tracks': 52,
 'num_albums': 47,
 'num_followers': 1,
 'tracks': [{'pos': 0,
   'artist_name': 'Missy Elliott',
   'track_uri': 'spotify:track:0UaMYEvWZi0ZqiDOoHU3YI',
   'artist_uri': 'spotify:artist:2wIVse2owClT7go1WT98tk',
   'track_name': 'Lose Control (feat. Ciara & Fat Man Scoop)',
   'album_uri': 'spotify:album:6vV5UrXcfyQD1wu4Qo2I9K',
   'duration_ms': 226863,
   'album_name': 'The Cookbook'},
  {'pos': 1,
   'artist_name': 'Britney Spears',
   'track_uri': 'spotify:track:6I9VzXrHxO9rA9A5euc8Ak',
   'artist_uri': 'spotify:artist:26dSoYclwsYLMAKD3tpOr4',
   'track_name': 'Toxic',
```

Looking at this playlist above, we can see that we have the following features:

> **Playlist Attributes**
>
> - Playlist Name
> - Playlist Type
> - Number of Tracks
> - Number of Unique Albums
> - Number of Followers
> - Number of Edits
> - Duration in Milliseconds
> - Number of Artists
>
> **Song Attributes**
>
> - Artist Name
> - Track URI
> - Artist URI
> - Track Name
> - Album URI
> - Duration in Milliseconds
> - Album Name

Some features that will be important to our model will be track name, artist name, album name, and their respective URIs. These will help us get more detail about a song from Spotipy. Another piece that could be helpful is the number of followers. This shows us interest in a given playlist. If a playlist has a jumble of random songs that don't form a cohesive playlist, it will probably have less followers than a well-crafted playlist.

Below is a (reformatted) summary from the readme file provided with the [data (https://www.aicrowd.com/challenges/spotify-million-playlist-dataset-challenge/dataset_files)](https://www.aicrowd.com/challenges/spotify-million-playlist-dataset-challenge/dataset_files).

General Info

- Number of Playlists: 1,000,000
- Number of Tracks: 66,346,428
- Number of Unique Tracks: 2,262,292
- Number of Unique Albums: 734,684
- Number of Unique Artists: 295,860
- Number of Unique Titles: 92,944
- Number of Playlists with Descriptions: 18,760
- Number of Unique Normalized Titles: 17,381
- Average Playlist Length: 66.346428

Top Playlist Titles

- 10,000 country
- 10,000 chill
- 8,493 rap
- 8,481 workout
- 8,146 oldies

Top Tracks

- 46,574 HUMBLE. by Kendrick Lamar
- 43,447 One Dance by Drake
- 41,309 Broccoli (feat. Lil Yachty) by DRAM
- 41,079 Closer by The Chainsmokers
- 39,987 Congratulations by Post Malone

Top Artists

- 847,160 Drake
- 413,297 Kanye West
- 353,624 Kendrick Lamar
- 339,570 Rihanna
- 316,603 The Weeknd

As we see in the summary above, there are 1 million playlists with over 66 million songs. Within these playlists, there are 2.2 million unique songs, 734k unique albums, and 300k unique artists. There is a lot of data to work with here. The playlists are sorted into categories, with country and chill being the top, followed by rap and workout. Drake, Kanye West, and Kendrick Lamar are the 3 top artists. The next step in this process is to convert all of this json data to be compatible with python.

Section 3: Data Preparation

The first steps are to convert our JSON data to python and DataFrames. Once we have that, we need to unwrap our track data so it can be converted to a DataFrame, as well.

In [6]:

```
"""
This code was used to open 100 of the files in the dataset and app
We then select the top 100 playlists according to number of follow
cohesive playlists
"""

if os.path.exists('Data/Spotipy Custom DataFrames/spotify_playlist
    pass
else:
    ## Generate DataFrame for playlist data

100 rows × 11 columns

Now that we have aggregated our data, we can see that our track data is nested, which makes sense given we are using json data. In order to get this track data into a pandas dataframe, we will be using similar code to normalize our track data into its own dataframe. We will also pull in the playlist id so we know which track relates to which playlist for when we analyze or use SQL.

In [8]:

```
if os.path.exists('Data/Spotipy Custom DataFrames/unwrapped_track_
    pass
else:
    # Creating DataFrame for the tracks column in our playlist dat
    unwrapped_track_data = pd.DataFrame()

    # Adding playlist IDs to a list to be appended to the unwrappe
    index_list = spd_top100.index.tolist()
    pid = []

    # Using json_normalize to reformat the json data the DataFrame
    for item in range(0,len(spd_top100)):
         unwrapped_track_data = unwrapped_track_data.append(pd.jsc

    # Appending the playlist IDs to the pid list
    for row in range(0,len(spd_top100.index)):
        track=0
        while track<spd_top100['num_tracks'].iloc[row]:
            track+=1
            pid.append(index_list[row])

    # Adding the playlist IDs to the unwrapped track data
    unwrapped_track_data['pid'] = pid

    # Save the data as a pickle file
    unwrapped_track_data.to_pickle('Data/Spotipy Custom DataFrames
```

In [9]:
```
# Call the pickle file for data use
unwrapped_track_data = pd.read_pickle('Data/Spotipy Custom DataFra
unwrapped_track_data
```

Out[9]:

Now that I have my data prepared into tables, we will need to import some relevant features that describe the type of each song. While we have already have many features that describe the music, such as song name, length and artist, none of these describe the *charactaristics* of each song. To do this, I have imported the Spotipy library. Per Spotipy's website, this library is described as "a lightweight Python library for the Spotify Web API. With Spotipy you get full access to all of the music data provided by the Spotify platform."

We can use this library to get more information about each song, and therefore classify the type of playlist that we are listening to. The reason we have to do this is because the playlist names might not always have a good description of the type of playlist we have. For example, playlist 159077 above is labelled "Rock Hits!", but playlist 154640 is just labelled an arbitrary title, "Thankful.". We can name Rock songs, but "Thankful" songs can be more subjective, and it is harder to classify a sound or vibe from the title alone. Once we have the type of playlist that we are looking at, we can begin suggesting songs from a similar genre or "vibe".

We will be using the API to import thhe following:

1. Audio features that analyze the sound/vibe of the song
2. Genre for each song
3. Popularity of each song

3.1 Audio Features DataFrames

In [14]:
```
# Using the audio_features method to get characteristics of our sc
sp.audio_features('0UaMYEvWZi0ZqiDOoHU3YI')
```

Out[14]:
```
[{'danceability': 0.904,
  'energy': 0.813,
  'key': 4,
  'loudness': -7.105,
  'mode': 0,
  'speechiness': 0.121,
  'acousticness': 0.0311,
  'instrumentalness': 0.00697,
  'liveness': 0.0471,
  'valence': 0.81,
  'tempo': 125.461,
  'type': 'audio_features',
  'id': '0UaMYEvWZi0ZqiDOoHU3YI',
  'uri': 'spotify:track:0UaMYEvWZi0ZqiDOoHU3YI',
  'track_href': 'https://api.spotify.com/v1/tracks/0UaMYEvWZi0ZqiDOoH
U3YI',
  'analysis_url': 'https://api.spotify.com/v1/audio-analysis/0UaMYEvW
Zi0ZqiDOoHU3YI',
  'duration_ms': 226864,
  'time_signature': 4}]
```

Above, Spotipy gives us relevant audio features for each song:

- **Danceability**: describes how suitable a track is for dancing based on a combination of musical elements including tempo, rhythm stability, beat strength, and overall regularity. A value of 0.0 is least danceable and 1.0 is most danceable.
- **Acousticness**: A measure from 0.0 to 1.0 of whether the track is acoustic.
- **Energy**: a measure from 0.0 to 1.0 and represents a perceptual measure of intensity and activity. Typically, energetic tracks feel fast, loud, and noisy.
- **Instrumentalness**: Predicts whether a track contains no vocals. The closer the instrumentalness value is to 1.0, the greater likelihood the track contains no vocal content.
- **Liveness**: Detects the presence of an audience in the recording. Higher liveness values represent an increased probability that the track was performed live.
- **Loudness**: The overall loudness of a track in decibels (dB). Loudness values are averaged across the entire track. Values typical range between -60 and 0 db.
- **Speechiness**: detects the presence of spoken words in a track. The more exclusively speech-like the recording (e.g. talk show, audio book, poetry), the closer to 1.0 the attribute value.
- **Tempo**: The overall estimated tempo of a track in beats per minute (BPM). In musical terminology, tempo is the speed or pace of a given piece and derives directly from the average beat duration.
- **Valence**: A measure from 0.0 to 1.0 describing the musical positiveness conveyed by a track. Tracks with high valence sound more positive (e.g. happy, cheerful, euphoric), while tracks with low valence sound more negative (e.g. sad, depressed, angry).

3.2 Genre DataFrames

Spotipy does not have a method to call genre for an individual song, so we will need to try our best in order to extract genre for an artist's music. I will create a function that gets the overall artist genre, which we can then apply to their songs. One possible downfall is if an artist goes across multiple genres, the songs might be mapped incorrectly.

3.4 Create Playlist/Track Vectors for Modeling

Now that we have our general information tables, it is time to createe our vectors for our recommendation system. We will make a Features, popularity, and genre vector for both our track data, and then we will use spark to aggregate the data and group it by playlist. All columns will be numeric.

3.4.1.1 Track Features Vector

In [39]:
```
# Combine track features with base list to get track_uri

playlist_features_by_track = """SELECT *
                    FROM track_features as tf
                    LEFT JOIN spd_top100 as spd
                        ON tf.playlist_id = spd.pid"""
```

In [40]:
```
# Convert to DataFrame
playlist_features_by_track = pd.read_sql(playlist_features_by_trac
```

In [41]:
```
# View DataFrame to determine columns to drop
playlist_features_by_track
```

Out[41]:

	playlist_id	track_uri	track_name	artist_name	artist_

Section 4: Modeling

Content-Based Filtering using Cosine Similarity

Now that we have our vectors with our audio features, popularity, and genre data, I will use cosine similarity to build our recommendation system. Here is how it will work:

- Step 1: Our model will take a look at a selected playlist id and its vector to analyze the overall features of the songs within.
- Step 2: Our model will then compare the playlist's vector to our unique track data vector (audio feaures, popularity, and genre) to generate a list of x number of songs (user-inputted) that are closely comparable to the playlist vectors, using cosine similarity. The greater the cosine similarity, the more similar the vectors are related.
- Step 3: We will then analyze the features of the top song generated for reasonableness.

How can I review results when there aren't many metrics available for content-based filtering? First, I will review the overall features for our selected playlist and compare them to the top track selected by our recommendation system for reasonableness. Second, I will plot the feature scores against each other to visualize the magnitude of difference between the average playlist scores and the top recommended song. Lastly, I will listen to a selection of 3 songs on each playlist, and then I will listen to and analyze the tracks provided by our recommendation system to subjectively determine whether I think they could belong on the playlist.

As we can see above, the aggregate difference between our recommended songs and our playlist average is 14, which is driven mainly by the genre data. This metric is only useful when compared to other aggregate differences, so I will analyze when I review another playlist. While it can be argued that our genre data is so specific that it is dominating our model, I personally think the specificity of the genre helps us narrow our recommendations down to suggest more accurate songs.

Looking at our visualization, for the most part it appears that our features for our recommendations are comparable to the playlist, with Tempo driving the main difference.

Now for the sound test. I will document my subjective findings below:

Some Nights, Radioactive, and Somebody That I Used to Know were all hits around 2013, and I personally have listened to these songs already. My description of Radioactive is an arena rock, bass thumping anthem that brings a high level of intensity. Some Nights and Somebody That I Used to Know are more chill and have a very nostaglic sound to them.

For our recommendations, What Goes Around..., Bang Bang You're Dead, Dirty Little Secret and Mess Around are all alternative/rock sounding tracks, whereas Piledriver Waltz is definitely more on the chill side.

Overall, based on our genre analysis and feature comparison, I would deem that these 5 recommended songs pass the reasonableness test.

As we can see above, the aggregate difference between our recommended songs and our playlist average is 6, which is driven mainly by the genre data. Most of our songs here are Disney/Soundtrack, so there seems to be little variation here. This aggregate difference is better than our first playlist, although it seems our features may be offsetting some of that difference.

Looking at our visualization, for the most part it appears all of the features are comparable, with teempo, energy, popularity, loudness and danceability having the largest difference. Seeing that the general theme of this playlist seems to be soundtrack for childrens movies, I believe that genre is the most important driver of the recommender here, and it seems like our genre hit the mark.

Now for the sound test. I will document my subjective findings below:

As we can see from our selection of songs, they all seem to be Disney songs from Moana and Tangled. I would expect that our recommendation system would suggest other kids songs accross childrens movies. After pulling more songs from the unwrapped track data, I can confirm that there are some songs that are not Disney.

For our recommendations, all 10 songs appear to be soundtrack songs, which is great, and they are all mainly from beloved kids movies. Because it seems like kids movies is the most category for this playlist, I will deem this recommendation adequate.

Overall, I would deem that these 10 recommended songs pass the reasonableness test.

As we can see above, the aggregate difference between our recommendations and our playlist data is pretty large, at 44. I believe this is driven by our genre data, as it is very evenly spread our across multiple genres

According to our feature visualization, our differences are very minimal compared to the other playlists. The largest differences are Speechiness, Acousticness and Energy.

Now for the sound test. I will document my subjective findings below:

From our playlist, I already recognize M83, the Black Keys and Vampire Weekend. Outro by M83 is very spacy and slow, whereas Howlin' For You is more uptempo and rock themed. Oxford Comma is also uptempo and kind of spaced out, but overall sounds chill. Not Just a Girl is slower paced, but also sounds like alt-rock overall. For our recommendations, I would expect chiller alt-rock that is slower in pace and has mostly fleshed out instrumentals.

For our recommendations, I recognize none of the songs. Caves, Coast to Coast and Diversion are very Indie sounding, somewhat Alternative. The two songs by Shlohmo are dance-like, and sound more electronic. They are also instrumentals. Outro by M83 fits a similar vibe to these songs.

This playlist seems like there is more variety between the genres, and as such, my recommendations also seem varied. However, due to the feature difference being relatively small, and due to the genres fitting the broad scope of the playlist, I deem these recommendations sufficient.

Section 5: Results

To summarize: using cosine similarity, I was able to successfully create a recommendation system using a selection of data from the Spotify Million Playlist Dataset. Overall, I have identified 3 potential drawbacks that might affect this model: 1. Suggesting songs from the same basket that the machine is learning from may create bias, 2. There are few metrics to assess our system, which makes it harder to determine the broader success of the model, 3. I analyzed the model using subjectivity. Tastes can be very different and subjectivity begets bias, as well. With these in mind, however, I beleive that this recommendation system is adequate at suggesting similar songs based on our tests in the results section.

As shown in the results section, our music recommendations seem to be driven mainly by the genre. Extracting Genre data from Spotipy provided us with very specific genre data that might've been able to isolate our list to a very select handful of songs. It then used the audio features and popularity vectors to differentiate the songs when it came to using cosine similarity.

I believe some good improvements to this project would be to source more general genre data if it is eventually made available as an export from Spotipy. As I had to manually export the data from Spotipy usng different means, it is hard to tell how accurate the genre data actually is. I would also like to include information on the year released, in case a playlist is related to a certain year, for example, 2013s hits. I would also like user-review data that shows how much a user liked a song, so I could try a collaborative-based filtering approach. Another thing I would like to do is research other forms of content-based recommendation systems, perhaps some form of clustering. Lastly, if I had a faster computer I would include all of the playlists in my analysis to capture more songs for my recommendation system.
